The Oral cavity: Divisions and Boundaries.

Tongue and Palate

Teeth, tooth morphology and Neurovascular supply

Olaleye O.O.
2B10
Objectives

• Understand the regions and boundaries of the oral cavity
• Know the major anatomic features of the lips, cheeks, and gingivae
• Describe the external features of the tongue
• Outline the intrinsic and extrinsic muscles of the tongue and their movements
• Describe the hard and soft palate and their anatomic features
• Describe the anatomy of the oral cavity related to the soft palate
• Know the muscles of the soft palate, their movements, and their innervation
• Outline the vascular supply and innervation of the palate
• Describe the parotid, submandibular, and sublingual salivary glands, including their vascular supply and innervation
Oral cavity

Is inferior to the nasal cavities.
Has a roof and a floor.
It is continuous with the cavity of the pharynx posteriorly at the OROPHARYNGEAL ISTHMUS.
Its roof consists of the hard and soft palates.
The floor is formed mainly of soft tissues, which include:
-Muscular diaphragm
-and the tongue.
The roof of the oral cavity consists of the hard and soft palates.

The floor is formed mainly of soft tissues, which include a muscular diaphragm and the tongue.

The **lateral walls** (cheeks) are muscular and merge anteriorly with the lips surrounding the **oral fissure** (the anterior opening of the oral cavity).

The posterior aperture of the oral cavity is the **oropharyngeal isthmus**, which opens into the oral part of the pharynx.
The oral cavity is separated into two regions by the upper and lower dental arches consisting of the teeth and alveolar bone that supports them.

• the outer **ORAL VESTIBULE**, which is horseshoe shaped, is between the dental arches and the deep surfaces of the cheeks and lips-the oral fissure opens into it and can be opened and closed by muscles of facial expression, and by movements of the lower jaw;

• the inner **ORAL CAVITY PROPER**, which is enclosed by the dental arches.

The oropharyngeal isthmus at the back of the oral cavity proper can be opened and closed by surrounding soft tissues, which include the soft palate and tongue.
Oral Vestibule and Oral cavity proper
The oral cavity has multiple functions:

• it is the inlet for the digestive system involved with the initial processing of food, which is aided by secretions from salivary glands;

• it manipulates sounds produced by the larynx and one outcome of this is speech;

• it can be used for breathing because it opens into the pharynx, which is a common pathway for food and air. For this reason, the oral cavity can be used by physicians to access the lower airway, and dentists use 'rubber dams' to prevent debris such as tooth fragments from passing through the oropharyngeal isthmus and pharynx into either the esophagus or the lower airway.
Innervation of the Oral Cavity
General sensory innervation is carried predominantly by branches of the trigeminal nerve [V]:

• the upper parts of the cavity, including the palate and the upper teeth, are innervated by branches of the maxillary nerve [V$_2$];

• the lower parts, including the teeth and oral part of the tongue, are innervated by branches of the mandibular nerve [V$_3$];
Innervation contd:

• Taste (special afferent-SA) from the oral part or anterior two-thirds of the tongue is carried by branches of the facial nerve [VII], which join and are distributed with branches of the trigeminal nerve [V];

• Parasympathetic fibers to the glands within the oral cavity are also carried by branches of the facial nerve [VII], which are distributed with branches of the trigeminal nerve [V];

• Sympathetic fibers in the oral cavity ultimately come from spinal cord level T1, synapse in the superior cervical sympathetic ganglion, and are eventually distributed to the oral cavity along branches of the trigeminal nerve [V] or directly along blood vessels.
- All muscles of the tongue are innervated by the **HYPOGLOSSAL NERVE [XII]**,

- Except the **PALATOGLOSSUS muscle**; **vagus nerve [X]**.

- Muscles of the soft palate are innervated by the **vagus nerve [X]**

- Except for the tensor veli palatini; branch from the **mandibular nerve [V₃]**.

- The muscle, mylohyoid, that forms the floor of the oral cavity is also innervated by the **mandibular nerve [V₃]**.
OSTEEOLOGY OF THE ORAL CAVITY
Bones that contribute to the skeletal framework of the oral cavity are related to the anatomy of structures in the oral cavity, they include:

• the paired **MAXILLAE**, and **PALATINE** and **TEMPORAL** bones;

• the unpaired **MANDIBLE**, **SPHENOID**, and **HYOID** bone.

In addition, the cartilaginous parts of the pharyngotympanic tubes on the inferior aspect of the base of the skull are related to the attachment of muscles of the soft palate.

Walls, the cheeks:

Forms the walls of the oral cavity

Each cheek consists of

• fascia muscle and

• a layer of skeletal muscle;

sandwiched between skin externally and oral mucosa internally. The thin layer of skeletal muscle within the cheeks is principally the buccinator muscle.
Floor of the O.C.
A muscular diaphragm, which fills the u-shaped gap between the left and right sides of the body of the mandible and is composed of the paired mylohyoid muscles;
1. Two cord-like **geniohyoid muscles** above the diaphragm, which run from the mandible in front to the hyoid bone behind;
The floor of the oral cavity proper is formed mainly by three structures.

1. A muscular diaphragm, which fills the u-shaped gap between the left and right sides of the body of the mandible and is composed of the paired *mylohyoid* muscles;

2. Two cord-like *geniohyoid muscles* above the diaphragm, which run from the mandible in front to the hyoid bone behind;

3. The *tongue*, which is superior to the geniohyoid muscles.

Also present in the floor of the oral cavity proper are salivary glands and their ducts.

The largest of these glands, on each side, are the sublingual gland and the oral part of the submandibular gland.

Tongue and Palate
The tongue is a muscular structure that forms part of the floor of the oral cavity and part of the anterior wall of the oropharynx.

Its anterior part is in the oral cavity and is somewhat triangular in shape with a blunt apex of tongue.

The apex is directed anteriorly and sits immediately behind the incisor teeth.

The root of tongue is attached to the mandible and the hyoid bone.

The superior surface of the oral or anterior two-thirds of the tongue is oriented in the horizontal plane.
The **pharyngeal surface or posterior one-third** of the tongue curves inferiorly and becomes oriented more in the vertical plane.

The oral and pharyngeal surfaces are separated by a V-shaped *terminal sulcus of tongue*.

This terminal sulcus forms the inferior margin of the oropharyngeal isthmus between the oral and pharyngeal cavities.

At the apex of the V-shaped sulcus is a small depression (the **foramen caecum of tongue**), which marks the site in the embryo where the epithelium invaginated to form the thyroid gland.
Papillae

The superior surface of the oral part of the tongue is covered by hundreds of papillae:

1. **Filiform papillae** are small cone-shaped projections of the mucosa that end in one or more points;

2. **Fungiform papillae** are rounder in shape and larger than the filiform papillae, and tend to be concentrated along the margins of the tongue;

3. **Vallate papillae**, the largest of the papillae, which are blunt-ended cylindrical papillae in invaginations in the tongue's surface-there are only about 8 to 12 vallate papillae in a single v-shaped line immediately anterior to the terminal sulcus of tongue;

4. **Foliate papillae** are linear folds of mucosa on the sides of the tongue near the terminal sulcus of tongue.
Filiform papillae are small cone-shaped projections of the mucosa that end in one or more points;
**Fungiform papillae** are rounder in shape and larger than the filiform papillae, and tend to be concentrated along the margins of the tongue.
**Vallate papillae**, the largest of the papillae, which are blunt-ended cylindrical papillae in invaginations in the tongue's surface—there are only about 8 to 12 vallate papillae in a single v-shaped line immediately anterior to the terminal sulcus of tongue;
Foliate papillae are linear folds of mucosa on the sides of the tongue near the terminal sulcus of tongue.
In conclusion;

The papillae in general increase the area of contact between the surface of the tongue and the contents of the oral cavity. All except the filiform papillae have taste buds on their surfaces.
**Inferior surface of tongue**

The under surface of the oral part of the tongue lacks papillae, but does have a number of linear mucosal folds. A single median fold (the *frenulum of tongue*) is continuous with the mucosa covering the floor of the oral cavity, and overlies the lower margin of a midline sagittal septum, which internally separates the right and left sides of the tongue. On each side of the frenulum is a lingual vein, and lateral to each vein is a rough *fimbriated fold*. 
Mucosa covering the pharyngeal surface of the tongue is irregular in contour because of the many small nodules of lymphoid tissue in the submucosa. These nodules are collectively called the LINGUAL TONSIL.

NB: There are no papillae on the pharyngeal surface.
MUSCLES OF THE TONGUE
The bulk of the tongue is composed of muscle.

The tongue is completely divided into a left and right half by a median sagittal septum composed of connective tissue.

This means that all muscles of the tongue are paired.

*There are intrinsic and extrinsic lingual muscles.*

Except for the palatoglossus, which is innervated by the vagus nerve [X], all muscles of the tongue are innervated by the hypoglossal nerve [XII].
Intrinsic muscles

The intrinsic muscles of the tongue originate and insert within the substance of the tongue. They are divided into:

- superior longitudinal,
- inferior longitudinal,
- transverse,
- vertical muscles
They alter the shape of the tongue by:

• lengthening and shortening it;

• curling and uncurling its apex and edges;

• flattening and rounding its surface.

Working in pairs or one side at a time the intrinsic muscles of the tongue contribute to precision movements of the tongue required for speech, eating, and swallowing.
Extrinsic muscles

Extrinsic muscles of the tongue originate from structures outside the tongue and insert into the tongue. There are **four** major extrinsic muscles on each side;

• Genioglossus

• Hyoglossus

• Styloglossus

• Palatoglossus.

These muscles protrude, retract, depress, and elevate the tongue.
Genioglossus

- Thick fan-shaped muscle which make a substantial contribution to the structure of the tongue.
- They occur on either side of the midline septum that separates left and right halves of the tongue.
- Originate from the superior mental tubercles on the posterior surface of the mandibular symphysis immediately superior to the origin of the geniohyoid muscles from the inferior mental tubercles. From this small site of origin, each muscle expands posteriorly and superiorly.
- The most inferior fibers attach to the hyoid bone. The remaining fibers spread out superiorly to blend with the intrinsic muscles along virtually the entire length of the tongue.
The genioglossus muscles:

• *depress the central part of the tongue;*

• *protrude the anterior part of the tongue out of the oral fissure (i.e. 'stick the tongue out').*

Like most muscles of the tongue, the genioglossus muscles are innervated by the hypoglossal nerves [XII].
Hyoglossus

- They are thin **quadrangular** muscles lateral to the genioglossus muscles.
- Each hyoglossus muscle originates from the entire length of the greater horn and the adjacent part of the body of the **hyoid bone**. At its origin from the hyoid bone, the hyoglossus muscle is lateral to the attachment of the middle constrictor muscle of the pharynx.
- The muscle passes superiorly and anteriorly through the gap between the **superior constrictor**, **middle constrictor**, and **mylohyoid** to insert into the tongue lateral to the geniohyoid and medial to the styloglossus.
- It depresses the tongue.
- Innervated by the hypoglossal nerve [XII].
• It is an important landmark on the floor of the oral cavity: the lingual artery from the external carotid artery in the neck enters the tongue deep to the hyoglossus, between the hyoglossus and genioglossus;

• The hypoglossal nerve [XII] and lingual nerve (branch of the mandibular nerve [V₃]), from the neck and infratemporal fossa of the head, respectively, enter the tongue on the external surface of the hyoglossus.
Styloglossus

- Originate from the anterior surface of the styloid processes of the temporal bones.
- From here, each muscle passes inferiorly and medially through the gap between the middle constrictor, superior constrictor, and mylohyoid muscles to enter the lateral surface of the tongue where they blend with the superior margin of the hyoglossus and with the intrinsic muscles.
- They retract the tongue and pull the back of the tongue superiorly.
- They are innervated by the hypoglossal nerves [XII].
**Palatoglossus**

- Are muscles of the soft palate and the tongue.
- Originates from the under surface of the *palatine aponeurosis* and passes anteroinferiorly to the lateral side of the tongue.
- Elevate the back of the tongue
- Move the palatoglossal arches of mucosa toward the midline
- Depress the soft palate.

These movements facilitate closing of the oropharyngeal isthmus and as a result separate the oral cavity from the oropharynx.

Unlike other muscles of the tongue, but similar to most other muscles of the soft palate, the palatoglossus muscles are innervated by the *vagus nerves* [X].
**Vascular supply**

**Artery**

**Lingual** artery is the major artery to the tongue. It originates from the external carotid artery in the neck adjacent to the tip of the greater horn of the hyoid bone.

In addition to the tongue, the lingual artery supplies the sublingual gland, gingiva, and oral mucosa in the floor of the oral cavity.
**Veins**

**Dorsal** and **Deep** lingual veins.

The **deep lingual veins** are visible through the mucosa on the undersurface of the tongue. Although they accompany the lingual arteries in anterior parts of the tongue, they become separated from the arteries posteriorly by the hyoglossus muscles.

It joins the internal jugular vein in the neck.
Innervation

Innervation of the tongue is complex and involves a number of nerves.

**Glossopharyngeal nerve [IX]**
Taste (SA) and general sensation from the pharyngeal part of the tongue are carried by the glossopharyngeal nerve [IX].

**Lingual nerve**
General sensory innervation from the anterior two-thirds or oral part of the tongue is carried by the lingual nerve.

**Facial nerve [VII]**
Taste (SA) from the oral part of the tongue is carried into the central nervous system by the facial nerve [VII].

**Hypoglossal nerve [XII]**
All muscles of the tongue are innervated by the hypoglossal nerve [XII] except for the palatoglossus muscle, which is innervated by the vagus nerve [X].
Sensory

Anterior two-thirds (oral)
- general sensation
  mandibular nerve [V₃]
  via lingual nerve
- special sensation (taste)
  facial nerve [VII] via
  chorda tympani

Posterior one-third (pharyngeal)
- general and special
  (taste) sensation
  glosopharyngeal nerve [IX]

Motor

Hypoglossal nerve [XII]
- Intrinsic muscle
  Genioglossus
  Hyoglossus
  Styloglossus

The roof of the oral cavity consists of the palate, which has two parts:

- anterior hard palate
- posterior soft palate
Hard palate

Separates the oral cavity from the nasal cavities.

It consists of a bony plate covered above and below by mucosa:

• above, it is covered by respiratory mucosa and forms the floor of the nasal cavities;
• below, it is covered by a tightly bound layer of oral mucosa and forms much of the roof of the oral cavity.
The palatine processes of the maxillae form the anterior three-quarters of the hard palate.

The horizontal plates of the palatine bones form the posterior one-quarter.

In the oral cavity, the upper alveolar arch borders the hard palate anteriorly and laterally.

Posteriorly, the hard palate is continuous with the soft palate.

The mucosa of the hard palate in the oral cavity possesses numerous transverse palatine folds (palatine rugae) and a median longitudinal ridge (palatine raphe), which ends anteriorly in a small oval elevation (incisive papilla).

The incisive papilla overlies the incisive fossa formed between the horizontal plates of the maxillae immediately behind the incisor teeth.
SOFT PALATE

Continues posteriorly from the hard palate and acts as a valve that can be:

• depressed to help close the oropharyngeal isthmus;
• elevated to separate the nasopharynx from the oropharynx.

The soft palate is formed and moved by four muscles and is covered by mucosa that is continuous with the mucosa lining the pharynx and oral and nasal cavities. The small tear-shaped muscular projection that hangs from the posterior free margin of the soft palate is the **uvula**.

The tensor veli palatini muscle is composed of two parts;
• vertical muscular part;
• and a more horizontal fibrous part, which forms the palatine aponeurosis
Levator veli palatini
Teeth

They are attached to sockets or alveoli in two elevated arches of bone;

• mandible below and

• maxillae above (alveolar arches).

If the teeth are removed, the alveolar bone is resorbed and the arches disappear.

The gingivae or gums are specialized regions of the oral mucosa that surround the teeth and cover adjacent regions of the alveolar bone. The different types of teeth are distinguished on the basis of morphology, position, and function.
• the incisor teeth are the 'front teeth' and have one root and a chisel-shaped crown, they are used for cutting;

• the canine teeth are posterior to the incisors, they are the longest teeth, have a crown with a single pointed cusp, and they are for grasping.

• the premolar teeth (bicuspids) have a crown with two pointed cusps, one on the buccal (cheek) side of the tooth and the other on the lingual (tongue) or palatal (palate) side. Generally they have one root (but the upper first premolar next to the canine may have two), and they are for grinding;

• the molar teeth are behind the premolar teeth, they have three roots and crowns with three to five cusps, and they are for grinding.
Two successive sets of teeth develop in humans, deciduous teeth (baby teeth) and permanent teeth (adult teeth). The deciduous teeth emerge from the gingivae at between six months and two years of age.

Permanent teeth begin to emerge and replace the deciduous teeth at around age six years, and can continue to emerge into adulthood.
The 20 deciduous teeth consist of

• two incisor,

• one canine, and

• two molar teeth on each side of the upper and lower jaws.

These teeth are replaced by the incisor, canine, and premolar teeth of the permanent teeth. The permanent molar teeth erupt posterior to the deciduous molars and require the jaws to elongate forward to accommodate them.
**Vessels**

**Arteries**

All teeth are supplied by vessels that branch either directly or indirectly from the maxillary artery.

**Inferior alveolar artery**: All lower teeth are supplied by the inferior alveolar artery, which originates from the maxillary artery in the infratemporal fossa and divides opposite the first premolar into **incisor** and **mental branches**. The mental branch leaves the mental foramen to supply the chin, while the incisor branch continues in bone to supply the anterior teeth and adjacent structures.

**Anterior and posterior superior alveolar arteries**

All upper teeth are supplied by anterior and posterior superior alveolar arteries.
Veins

Veins from the upper and lower teeth generally follow the arteries. **Inferior alveolar veins** from the lower teeth, and **superior alveolar veins** from the upper teeth drain mainly into the **pterygoid plexus of veins** in the infratemporal fossa, although some drainage from the anterior teeth may be via tributaries of the facial vein.

The **pterygoid plexus** drains mainly into the maxillary vein and ultimately into the **retromandibular vein** and jugular system of veins. In addition, small communicating vessels pass superiorly, from the plexus, and pass through small emissary foramina in the base of the skull to connect with the cavernous sinus in the cranial cavity. *Infection originating in the teeth can track into the cranial cavity through these small emissary veins.* Venous drainage from the teeth can also be via vessels that pass through the mental foramen to connect with the facial vein.
**Innervation**

All nerves that innervate the teeth are branches of the trigeminal nerve [V].

**Inferior alveolar nerve:** The lower teeth are all innervated by branches from the inferior alveolar nerve, which originates in the infratemporal fossa from the mandibular nerve [V₃]. Branches to the back teeth originate directly from the inferior alveolar nerve. Adjacent to the first premolar tooth, the inferior alveolar nerve divides into incisive and mental branches:

- the **incisive branch** innervates the first premolar, the canine, and the incisor teeth, together with the associated vestibular (buccal) gingiva;
- the **mental nerve** exits the mandible through the mental foramen and innervates the chin and lower lip.
Anterior, middle, and posterior superior alveolar nerves: All upper teeth are innervated by the anterior, middle, and posterior superior alveolar nerves, which originate directly or indirectly from the maxillary nerve \([V_2]\).
Thank You
